## Examples of how to use functions

Kwame Okrah, Hector Bravo June 7, 2013

## 1 Overview of pipeline

The purpose of this pipeline is to streamline the process for analyzing RNA-seq data with potential batch effects. The pipeline includes 1) quantile normalization 2) log-transformation of counts 3) combat (location) batch correction 4) voom calculation of weights.

The functions in this package can be grouped into two main categories:

- 1. The functions used for assessing batch effects.
  - makeSVD
  - pcRes
  - plotPC
- 2. The functions for removing batch effect and computing weights for limma.
  - qNorm
  - log2CPM
  - voomMod
  - combatMod
  - batchSEQ\*

Below we will illustrie how to use these functions using the pasilla data set.

**note**: All the functions in this package have a detailed help file which tells you what kind of objects go in and what kind of objects come out. It is important to look at these help files for each function.

## 2 Examples of how to use the functions

We will use the pasilla dataset found in the pasilla package. (This is the same dataset used in the DESeq vignette)

```
> require(pasilla)
> # locate the path of the dataset and read in the dataset
> datafile = system.file("extdata/pasilla_gene_counts.tsv", package="pasilla")
> counts = read.table(datafile, header=TRUE, row.names=1)
> head(counts)
```

<sup>\*</sup> batchSEQ is the pipeline function. It combines qNorm, log2CPM, voomMod, and combatMod into one step.

```

> counts = counts[rowSums(counts) > ncol(counts),]
> dim(counts)
[1] 10153
```

In this dataset there are two biological conditions: treated (3 samples) and untreated (4 samples). Two samples are single-end and the other 4 are paired-end. We will use sigle-end and paired-end as bathch effects. Below is the design (pheno data.frame).

```
> design = data.frame(row.names=colnames(counts),
                       condition=c("untreated", "untreated", "untreated",
                                   "untreated", "treated", "treated", "treated"),
                      libType=c("single-end", "single-end", "paired-end",
                                 "paired-end", "single-end", "paired-end", "paired-end"))
> design
           condition
                         libType
untreated1 untreated single-end
untreated2 untreated single-end
untreated3 untreated paired-end
untreated4 untreated paired-end
treated1
             treated single-end
treated2
             treated paired-end
treated3
             treated paired-end
```

#### 2.1 Explore data for batch effects

We will begin our analysis by exploring the data for possible/significant batch effects.

```
> # load batch package
> require(cbcbSEQ1)
> #
> # quantile normalize: adjust counts for library size.
> qcounts = qNorm(counts)
> # convert counts to log2 counts per milliom. (voom scale)
> cpm = log2CPM(qcounts)
> names(cpm)
```

```
[1] "y" "lib.size"
> libsize = cpm$lib.size
> cpm = cpm$y
> #
> # PCA analysis
> # returns a list with two components v and d.
> res = makeSVD(cpm)
```

We can now call pcRes and plotPC.

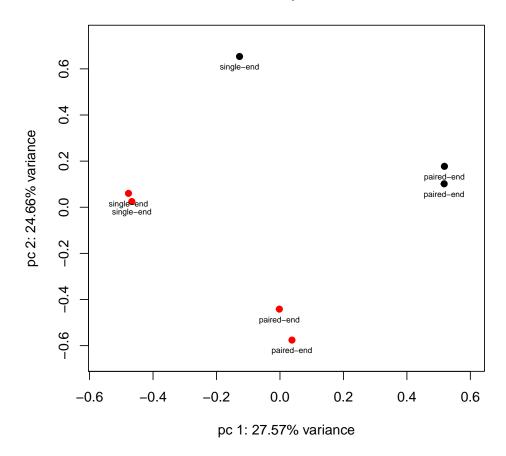

pcRes: computes variance of each principal component and how they "correlate" with batch and condition.

> pcRes(res\$v,res\$d, design\$condition, design\$libType)

```
propVar cumPropVar cond.R2 batch.R2
    27.57
               27.57

     9.46
               99.99
                         0.37
                                  0.65
```

• plotPC: Plot first 2 principal components. This function works like the regular plot function in R. ie. We can add all the options to make the plot sensible and well labelled. Below is an example:

### **PCA** plot

We see that there is a batch effect in the data. Both in the PCA "correlation" table and the PCA plot.

#### 2.2 Correct data for batch effects

The standard way to correct for batch effects will be to account for batch in the linear model. However we will use a modified version of combat instead. In this only adjust batch location. We do not adjust for scalar batch effects. This is because the data is not necessarily Gaussian. In order to account for scaling we have to take into account the mean var relationship inherent in this kind of data. We adjust batch location by removing the empirical beysian estimates of batch effects. (Future work)

- > # combatMod function
- > # noScale=TRUE option not to scale adjust
- > tmp = combatMod(cpm, batch=design\$libType, mod=design\$condition, noScale=TRUE)

#### Found 2 batches

Found 1 categorical covariate(s) Standardizing Data across genes Fitting 'shrunk' batch 1 effects Fitting 'shrunk' batch 2 effects Adjusting data for batch effects

```
> names(tmp)
[1] "bayesdata" "info"

#### 1538 / 10153

Let us now compare

the results to what we get when we adjust for bath in the model

```
> cond=design$condition
> batch=design$libType
> mod = model.matrix(~cond+batch ,
                     contrasts.arg=list(cond="contr.treatment", batch="contr.sum"))
> v1 = voom(counts, mod)
> fit1 = lmFit(v1)
> eb1 = eBayes(fit1)
> top1 = topTable(eb1, coef=2, n=nrow(v1$E))
Compare results results:
> tab = merge(top[,c("ID", "adj.P.Val")], top1[,c("ID", "adj.P.Val")], by="ID")
> as.data.frame(table(combat = tab[,2] < 0.05, model = tab[,3] < 0.05))
  combat model Freq
  FALSE FALSE 8516
   TRUE FALSE 401
3
 FALSE TRUE
                 99
   TRUE TRUE 1137
```

We gain slightly more with combat.
